

Case Study

SA Recycling relies on Sensor Sorting Technology by STEINERT

Edited by on 23. Jan. 2024

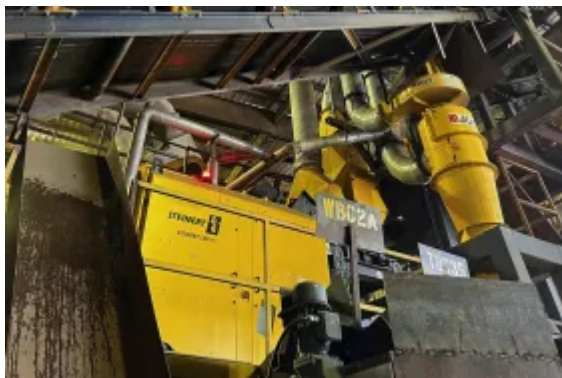

USA based SA Recycling processes 6 million metric tons of residential and commercial scrap metal every year at more than 140 sites. In a recent conversation, George Adams, CEO of SA Recycling, shared insights into the company's growth, sustainability efforts, and the significant role of STEINERT technology in their operations. Omar Bravo, General Manager of the Anaheim plant in California, highlights the ground-level innovations driving the company's success.

Adams, who has been in the recycling field since he was 17, humbly stated, "I began driving tow trucks when I was 17. Later I started working alongside my father for 40 something years. My two brothers also work in the company and are my partners and after all these years we're still really close. Then, my sons came into the business after they finished college. So, I guess that's what makes it the most fun. It's working with my sons."

Ultimately, however, it is George Adams' leadership, which has been fundamental in steering SA Recycling to remarkable success. Adams' participation in global recycling organisations such as ISRI and BIR highlight the company's dedication to both recycling and navigating global political terrain to ensure sustainability worldwide.

SA Recycling's journey started in Anaheim, California, where today 250,000 metric tonnes of shredded materials are processed a year. Adams recalls the evolution and expansion of the company's facilities, highlighting Anaheim as a hub for research and development for SA. "As recyclers, we are always looking for better ways to recover materials," says Omar Bravo. "President George Adams has researched and purchased higher technology equipment to achieve this goal."

Highly reliable Sorting Systems for processing light and heavy Metals

A STEINERT CHUTEC chute sorter uses X-ray fluorescence technology for sorting fine heavy metals with grain sizes down to 5mm. (Pictures: ©STEINERT GmbH)

In terms of recycling capabilities, Adams praised the company's relationship with STEINERT. "We have utilised their eddy current separators for quite some time now in many of our locations to get most of our non-ferrous metals. For approximately four years, we have also been using their multi-sensor sorters, primarily to upgrade Zorba to Twitch, meaning to extract an aluminum mix from a non-ferrous metal stream." The STEINERT KSS | XT CLI combines four sensors. Two optical sensors offer colour and three-dimensional shape data, while the inductive sensor identifies metals. Density variances are recognized using x-ray transmission (XRT). In the meantime, Omar Bravo points out the outstanding flexibility and accuracy: "Depending on which product our customer requires, we select the right program and sort up to 99% pure aluminium or eliminate magnesium from the product stream at the touch of a button."

X-ray fluorescence technology (XRF) is also in use in Anaheim. Since 2019, STEINERT CHUTEC XRF-sorter efficiently segregates heavy metals into metal types such as copper, brass, zinc or stainless steel, what opens up new sales potential for SA Recycling. Bravo: "I think we were the first recyclers in the US to have the Chutec and this opened up the doors for us for different markets."

While Omar Bravo appreciates the longevity of the X-ray sorters, of which he still hasn't had to replace a single sensor in four years, George Adams is particularly enthusiastic about the Eddy Current separators: "When we started measuring, the big thing was that they had a faster belt speed on their machine than what other people had. The even bigger thing is that over the years we have realised that we simply don't lose bearings on their eddy currents – they just don't break, ever".

Accurate Metal Segregation for a better Tomorrow

Several STEINERT KSS multi- sensor sorting systems with X-ray transmission technology generate high-purity aluminium products.

In George Adams' perspective, the future isn't just a destination, it's a complex journey. He emphasizes a comprehensive recycling ecosystem that extends beyond metal and proudly mentions their commitment to recycle everything - including water which they use in their yards and run it back to their shredders to conserve valuable resources. While he acknowledges solar power as a positive step, Adams focuses on maximizing metal recycling in order to reduce the greenhouse gases generated in the production of primary metals and thereby better serve the environment.

Through collaboration with technology pioneers like STEINERT, SA Recycling faces a future where precision, sustainability, and efficiency converge seamlessly. As he envisions the future of metal recycling, the CEO leans forward with confidence. He sees STEINERT's advancements in LIBS technology for aluminium alloy sorting as the direction the industry is heading - with an emphasis on precision separation to meet the demand for specialty alloys that are being returned to the US. "I think the harder thing right now is adapting to the next phase, which is using equipment to get specific segregated alloys. Because I think that's really going to be the future of metal recycling. Everybody wants segregated alloys."

George Adams recognises STEINERT's role in enhancing recycling processes, accenting the shared commitment of SA Recycling and STEINERT towards meeting evolving market demands. This collaboration demonstrates the

importance of cutting-edge German technology in advancing global recycling efforts. His confidence in STEINERT's capabilities reflects his deep belief in the German engineering behind it. "Made in Germany means something to me," says Adams with a nod. "STEINERT embodies that label perfectly."
